

## 0.1 Simulations

The correction factor is better estimated through a Montecarlo simulation.. If we denote as  $E$  the total energy of the three photons, we randomly divided the segment  $[0, E]$  into three parts  $E_1, E_2, E_3$ .

Discarding triplets that doesn't allow momentum conservation, we obtain a uniform distribution on all the possible energy triplets. Simulating also the three detectors and triggering on the triple coincidences, the ratio of observed events results:

$$c_{3\gamma} := \frac{\text{detected events}}{\text{total events}} \approx 5 * 10^{-4}$$

Figure 1: Correlation of the angles between first and second (x axis) and first and third (y axis) simulated photon.

With a similar calculation the ratio of observed events for the two-photons decay can be obtained:

$$c_{2\gamma} \approx 3.7 * 10^{-2}$$

Therefore the correction factor result:

$$c_f = \frac{c_{2\gamma}}{c_{3\gamma}} \approx 71 \quad (1)$$

From the simulation we can also assert that the dependence from  $R$  can be neglected in our rough results:  $c$  varies less than 10% for a  $R$  variation of 3%.

This lead to a ratio of about:

$$R = 387 \quad (2)$$
